Bringing Fossils to Life: An Introduction to Paleobiology; 1; the manufacture of numerous devices such as semiconductor integrated circuit chips (ICs), silicon devices, and thin-film magnetic recording heads, a pattern of photoresist (or other type of resist) is formed over the surface of a wafer or the like substrate to be processed. A pattern is defined by the use of a pattern mask or the like in which a masking material is imprinted with a desired pattern that defines the surface contour of a portion of the pattern to be formed over the wafer. By utilizing conventional photolithography techniques, a series of masking operations may be used to progressively refine the pattern to any degree of complexity desired. The application of the resist to the substrate is typically performed by one of a number of techniques. In a spin coating technique, the wafer is first spinning and then the resist is applied, followed by spinning and subsequently developing the resist. In a dip coating technique, the wafer is first dipped in a bath containing the resist (typically with a small amount of etchant, developing agent, etc.) and then removed. In a spray coating technique, the resist is spray coated over the wafer. In a stenciling technique, an open pattern is placed on
